Problem

Training distributed/federated learning models is typically performed by solving an optimization problem

$$\min_{x\in\mathbb{R}^d}\Big\{f(x)\stackrel{\text{def}}{=}\frac{1}{n}\sum_{i=1}^nf_i(x)\Big\},$$

- **x:** model parameters
- *d*: number of parameters (dimension)
- *n*: number of devices/machines/nodes/workers
- $f_i(x)$: loss function associated with data stored on device i

伺 ト イ ヨ ト イ ヨ ト

Examples

$$\min_{x \in \mathbb{R}^d} \left\{ f(x) \stackrel{\text{def}}{=} \frac{1}{n} \sum_{i=1}^n f_i(x) \right\}$$

Each device *i* stores *m* data samples $\{a_{i,j}, b_{i,j}\}_{j=1}^m \in \mathbb{R}^{d+1}$ ($b_{i,j}$ is the label of data $a_{i,j}$)

- Ordinary least squares: $f_i(x) = \frac{1}{m} \sum_{j=1}^m (a_{i,j}^T x b_{i,j})^2$
- Logistic regression: $f_i(x) = \frac{1}{m} \sum_{j=1}^m \log \left(1 + \exp(-b_{i,j} a_{i,j}^T x)\right)$

• SVM:
$$f_i(x) = \frac{1}{m} \sum_{j=1}^m \max(0, 1 - b_{i,j} a_{i,j}^T x) + \frac{\lambda}{2} ||x||_2^2$$

Goal

$$\min_{x \in \mathbb{R}^d} \left\{ f(x) \stackrel{\text{def}}{=} \frac{1}{n} \sum_{i=1}^n f_i(x) \right\}$$

Goal: find an ϵ -solution (parameters) \hat{x} , e.g., $f(\hat{x}) - f(x^*) \leq \epsilon$, where $x^* := \arg \min_{x \in \mathbb{R}^d} f(x)$.

Goal

$$\min_{x \in \mathbb{R}^d} \left\{ f(x) \stackrel{\text{def}}{=} \frac{1}{n} \sum_{i=1}^n f_i(x) \right\}$$

Goal: find an ϵ -solution (parameters) \hat{x} , e.g., $f(\hat{x}) - f(x^*) \leq \epsilon$, where $x^* := \arg \min_{x \in \mathbb{R}^d} f(x)$.

For distributed optimization methods:

Bottleneck: communication cost

Common strategy: compress the communicated messages (lower communication cost per communication round) and hope that this will not increase the total number of communication rounds.

周 ト イヨ ト イヨ ト 二 ヨ

• Several recent work show that the total communication complexity can be improved via **compression**. See, e.g., QSGD (Alistarh et al., NIPS'17), DIANA (Mishchenko et al., arXiv'19), Natural compression (Horváth et al., arXiv'19), and MARINA (Gorbunov et al., ICML'21).

A B + A B +

• Several recent work show that the total communication complexity can be improved via **compression**. See, e.g., QSGD (Alistarh et al., NIPS'17), DIANA (Mishchenko et al., arXiv'19), Natural compression (Horváth et al., arXiv'19), and MARINA (Gorbunov et al., ICML'21).

 However previous work usually lead to this kind of improvement: Communication cost per round (- -) Rounds (+) ⇒ Total (-)

'-' denotes decrease, '+' denotes increase

• However previous work usually lead to this kind of improvement: Communication cost per round (- -) Rounds (+) \Rightarrow Total (-)

'-' denotes **decrease**, '+' denotes **increase**

• Acceleration/Momentum of gradient-type methods is widely studied for achieving faster convergence rates (fewer iterations).

"Can distributed gradient-type methods theoretically benefit from the combination of **compression** and **acceleration**?"

イロン 不問 とくほと 不良 とうほう

• Recently, Li et al. (ICML'20)¹ gave the first successful combination of compression and acceleration by proposing **ADIANA** method.

¹Zhize Li, Dmitry Kovalev, Xun Qian, and Peter Richtárik. Acceleration for compressed gradient descent in distributed and federated optimization. In *ICML*, 2020.

- Recently, Li et al. (ICML'20)¹ gave the first successful combination of compression and acceleration by proposing **ADIANA** method.
- Some drawbacks:
 - They only provide theoretical results for strongly convex problems. (e.g., logistic regression is convex but not strongly convex)
 - ► The ADIANA method is also not applicable to general convex case.
 - Even if a problem is strongly convex, the modulus of strong convexity is typically not known, or hard to estimate properly.

¹Zhize Li, Dmitry Kovalev, Xun Qian, and Peter Richtárik. Acceleration for compressed gradient descent in distributed and federated optimization. In *ICML*, 2020.

Table: Communication rounds for finding an ϵ -solution $f(x^T) - f(x^*) \le \epsilon$

Algorithm	General convex	Remark
DIANA (Mishchenko et al., 2019)	$O\Big(ig(1+rac{\omega}{n}ig)rac{L}{\epsilon}+rac{\omega}{\epsilon}\Big)$	✓ compression× acceleration
CANITA (this paper)	$O\left(\sqrt{\left(1+\sqrt{\frac{\omega^3}{n}}\right)\frac{L}{\epsilon}}+\omega\left(\frac{1}{\epsilon}\right)^{\frac{1}{3}}\right)$	✓ compression✓ acceleration

L: L-smooth parameter $(\|\nabla f(x) - \nabla f(y)\| \le L \|x - y\|)$ ω : compression parameter (no compression implies $\omega = 0$) *n*: number of devices/machines/nodes/workers

Table: Communication rounds for finding an ϵ -solution $f(x^T) - f(x^*) \le \epsilon$

Algorithm	General convex	Remark
DIANA (Mishchenko et al., 2019)	$O\Big(ig(1+rac{\omega}{n}ig)rac{L}{\epsilon}+rac{\omega}{\epsilon}\Big)$	✓ compression× acceleration
CANITA (this paper)	$O\left(\sqrt{\left(1+\sqrt{\frac{\omega^3}{n}}\right)\frac{L}{\epsilon}}+\omega\left(\frac{1}{\epsilon}\right)^{\frac{1}{3}}\right)$	✓ compression✓ acceleration

L: L-smooth parameter $(\|\nabla f(x) - \nabla f(y)\| \le L \|x - y\|)$ ω : compression parameter (no compression implies $\omega = 0$) *n*: number of devices/machines/nodes/workers

• For example, if compression ratio is 0.1, then $\omega \approx 10$ (e.g. random sparsification). Further if $n = 10^6$ and $\epsilon = 10^{-6}$, then the result of our CANITA is $O(10^3)$, while the previous state-of-the-art DIANA is $O(10^6)$, i.e., $O(\sqrt{\frac{L}{\epsilon}})$ vs. $O(\frac{L}{\epsilon})$.

Our CANITA Algorithm

Our CANITA algorithm is based on the accelerated gradient method **ANITA** (Li, 2021)² which achieves the current state-of-the-art convergence result for **general convex** problems.

²Zhize Li. ANITA: An optimal loopless accelerated variance-reduced gradient method. *arXiv:2103.11333*, 2021.

ANITA vs. CANITA

ANITA (simplified)

1: for t = 0, 1, 2, ... do 2: $y^{t} = \theta_{t}x^{t} + (1 - \theta_{t})w^{t}$ 3: Randomly pick $i \in \{1, 2, ..., n\}$ 4: $g^{t} = \nabla f_{i}(y^{t}) - \nabla f_{i}(w^{t}) + \nabla f(w^{t})$ 5: $x^{t+1} = x^{t} - \frac{\eta_{t}}{\theta_{t}}g^{t}$ 6: $z^{t+1} = \theta_{t}x^{t+1} + (1 - \theta_{t})w^{t}$ 7: $w^{t+1} = \begin{cases} z^{t+1}, & \text{with probability } p_{t} \\ w^{t}, & \text{with probability } 1 - p_{t} \end{cases}$

8: end for

◆□▶ ◆□▶ ◆ □▶ ◆ □▶ ◆ □ ● ● ● ●

ANITA vs. CANITA

ANITA (simplified)

1: for t = 0, 1, 2, ... do

2:
$$y^t = \theta_t x^t + (1 - \theta_t) w^t$$

- 3: Randomly pick $i \in \{1, 2, \ldots, n\}$
- 4: $g^t = \nabla f_i(y^t) \nabla f_i(w^t) + \nabla f(w^t)$

5:
$$x^{t+1} = x^t - \frac{\eta_t}{\theta_t} g^t$$

6:
$$z^{t+1} = \theta_t x^{t+1} + (1 - \theta_t) w^t$$

7: $w^{t+1} = \begin{cases} z^{t+1}, & \text{with probability } p_t & 6: \\ w^t, & \text{with probability } 1 - p_t \end{cases}$

8: end for

• Compared with ANITA, our **CANITA** needs to deal with the extra compression of shifted local gradients in the distributed network.

• Hence, the obtained gradient estimator g^t ⁹: is substantially different and more complicated, 10: which necessitates a novel proof technique.

Our CANITA

4:

5:

1: for t = 0, 1, 2, ... do

2:
$$y^t = \theta_t x^t + (1 - \theta_t) w^t$$

3: for all nodes $i = 1, 2, ...$

- for all nodes $i = 1, 2, \dots, n$ do in parallel
- Compress the shifted local gradient $C(\nabla f_i(y^t) h_i^t)$ and send to the server Update the local shift $h_i^{t+1} = h_i^t + \alpha_t C(\nabla f_i(w^t) h_i^t)$

end for

Aggregate received compressed local gradient information:

$$g^{t} = h^{t} + \frac{1}{n} \sum_{i=1}^{n} C(\nabla f_{i}(y^{t}) - h_{i}^{t})$$

$$h^{t+1} = h^{t} + \alpha_{t} \frac{1}{n} \sum_{i=1}^{n} C(\nabla f_{i}(w^{t}) - h_{i}^{t})$$
8: $x^{t+1} = x^{t} - \frac{\eta_{t}}{\theta_{t}} g^{t}$
9: $z^{t+1} = \theta_{t} x^{t+1} + (1 - \theta_{t}) w^{t}$
10: $w^{t+1} = \begin{cases} z^{t+1}, & \text{with probability } p_{t} \\ w^{t}, & \text{with probability } 1 - p_{t} \end{cases}$
11: end for

Conclusion

• We propose the **first compressed and accelerated** gradient method **CANITA** for distributed **general convex** optimization.

• We show that CANITA provably enjoys the benefits of both **compression** (compressed communication in each round) and **acceleration** (much fewer communication rounds).

- Previous work (compression without acceleration): Communication cost per round (- -) Rounds (+) ⇒ Total (-)
- Our CANITA (compression and acceleration): Communication cost per round (- -) Rounds (- -) ⇒ Total (- - -)
