#### 2 Our Techniques

### Online Model Selection with Decentralized Data (OMS-DecD)

Protocol 1 OMS-DecD1: for  $t = 1, 2, \ldots, T$  do2: for  $j = 1, \ldots, M$  in parallel do3: The adversary sends  $\mathbf{x}_t^{(j)}$  to the j-th client4: The learner selects a hypothesis space  $\mathcal{F}_{I_t} \in \mathcal{F}$ 5: The learner selects  $f_t^{(j)} \in \mathcal{F}_{I_t}$  and outputs  $f_t^{(j)}(\mathbf{x}_t^{(j)})$ 6: The learner observes the true output  $y_t^{(j)}$ 7: end for8: end for

The learner aims to design an algorithm without leaking the raw data and minimizing the regret,

$$\forall i \in [K], \quad \operatorname{Reg}_{D}(\mathcal{F}_{i}) = \sum_{t=1}^{T} \sum_{j=1}^{M} \ell\left(f_{t}^{(j)}(\mathbf{x}_{t}^{(j)}), y_{t}^{(j)}\right) - \min_{f \in \mathcal{F}_{i}} \sum_{t=1}^{T} \sum_{j=1}^{M} \ell\left(f(\mathbf{x}_{t}^{(j)}), y_{t}^{(j)}\right).$$

## A Trivial Approach

## Definition 1 (A non-cooperative algorithm)

Let  $A_{OMS}$  be an algorithm for centralized online model selection. A non-cooperative algorithm for OMS-DecD is defined by independently running a copy of  $A_{OMS}$  on each client.

It is obvious that

- The regret bound is  $O(M \cdot \text{Reg}(\mathcal{A}_{OMS}))$ .
- The non-cooperative algorithm will not leak the raw data.

There is a pessimistic result [1]:

• if K = 1, then the non-cooperative algorithm is optimal in full information. In other words, collaboration is unnecessary in full information setting.

## Question 1

Whether collaboration is effective for OMS-DecD i.e.,  $K \ge 2$ . And if so, how?

## Our results

Algorithm	Regret	Computational constraint on clients
Any	$\Omega(M\sqrt{T\ln K})$	No
non-cooperative	$\Omega(M\sqrt{TKJ^{-1}})$	$O(J), 1 \le J < K$
FOMD-OMS	$\tilde{O}(M\sqrt{T\ln K} + \sqrt{MTKJ^{-1}})$	$O(J), 2 \leq J < K$

Table 1: Summary of the main results.

#### We can conclude that

- No computational constraints on clients.
  Collaboration is unnecessary for OMS-DecD.
- The per-round time complexity on each client is limited to o(K). Collaboration is necessary for OMS-DecD.
- The collaboration in previous federated algorithms for distributed online multi-kernel learning [2, 3] is unnecessary.

Junfan Li (HITSZ)

## Overview

Lower Bounds

- No computational constraint. Reducing OMS-DecD to prediction with expert advice. [4]
- The per-round time complexity on each client is limited to *o*(*K*). Reducing OMS-DecD to prediction with limited advice. [5]

Algorithm

- A new federated online mirror descent framework, FOMD-No-LU.
- Decoupling model selection and prediction for efficient communications.

Theoretical analysis

• A new Bernstein's inequality for martingale

high-probability regret bounds that adapt to the complexity of individual hypothesis space.

## Reducing to Prediction with Expert/Limited Advice

#### Theorem 2 (Lower Bounds)

Assuming that  $5 \le K \le \min\{d, T\}$ . For each  $i \in [K]$ , let  $\mathcal{F}_i = \{f_i(\mathbf{x}) = \mathbf{e}_i^\top \mathbf{x}\}$  and  $\mathcal{D}_i = [\min_{\mathbf{x} \in \mathcal{X}} f_i(\mathbf{x}), \max_{\mathbf{x} \in \mathcal{X}} f_i(\mathbf{x})]$ , where  $\mathbf{e}_i$  is the standard basis vector in  $\mathbb{R}^d$ . Denote by sup the supremum over all examples.

(i) There are no computational constraints on clients. Let  $\ell(v, y) = |v - y|$ . The regret of any algorithm for OMS-DecD satisfies:

 $\lim_{T\to\infty} \sup \max_{i\in[K]} \operatorname{Reg}_D(\mathcal{F}_i) \ge 0.25M\sqrt{T\ln K};$ 

(ii) The per-round time complexity on each client is limited to O(J). Let

 $\ell(v, y) = 1 - v \cdot y$ . The regret of any, possibly randomized, noncooperative algorithm with outputs in  $\bigcup_{i \in [K]} \mathcal{D}_i$  for OMS-DecD satisfies:

 $\sup \mathbb{E}[\max_{i \in [K]} \operatorname{Reg}_D(\mathcal{F}_i)] \ge 0.1M\sqrt{KTJ^{-1}}$ , where the expectation is taken over the randomization of algorithm.

## A New Bernstein's Inequality for Martingale

#### Lemma 3

Let  $X_1, \ldots, X_n$  be a bounded martingale difference sequence w.r.t. the filtration  $\mathcal{H} = (\mathcal{H}_k)_{1 \le k \le n}$  and with  $|X_k| \le a$ . Let  $Z_t = \sum_{k=1}^t X_k$  be the associated martingale. Denote the sum of the conditional variances by  $\sum_n^2 = \sum_{k=1}^n \mathbb{E} \left[ X_k^2 | \mathcal{H}_{k-1} \right] \le v$ , where  $v \in [0, B]$  is a random variable and  $B \ge 2$  is a constant. Then for any constant a > 0, with probability at least  $1 - 2\lceil \log B \rceil \delta$ ,

$$\max_{t=1,\ldots,n} Z_t < \frac{2a}{3}\ln\frac{1}{\delta} + \sqrt{\frac{2}{B}\ln\frac{1}{\delta}} + 2\sqrt{\nu\ln\frac{1}{\delta}}.$$

The novelty is that the conditional variance v is a random variable, not a constant.
